

Lab 4 task

LUHN Algorithm (Credit Card Validation)

- **Input:**

The user is asked to input a credit card number

.

- **Reversing the Card Number:**

The card number is converted to a string (if it's not already) and reversed. This is done because the Luhn algorithm works by starting from the right-most digit.

- **Iterating Over the Digits:**

A `for` loop is used to iterate through each digit of the reversed card number.

The `enumerate` function gives both the index `i` and the digit.

Double Every Second Digit:

For every second digit (starting from the right), i.e., at indices 1, 3, 5, ..., the digit is doubled.

If the doubled value is greater than 9, 9 is subtracted from it to get a valid value for that digit (this is part of the Luhn checksum rule).

- **Summing the Digits:**

The sum of all digits (after the transformation) is calculated in `total`.

Validation:

After the loop, the function checks if the sum (`total`) is divisible by 10.

If it is, the card number is valid; otherwise, it's invalid.

- **Output:**

Based on the result of `luhn_algorithm()`, the program prints whether the card number is valid or invalid.

Remove Punctuation from a String

Import `string` Module:

Function to Remove Punctuation:

This function takes the input string and removes all punctuation using the `translate()` method.

This creates a translation table that maps all punctuation characters to `None` (i.e., removes them).

Input:

The program asks the user to input a string.

Remove Punctuation:

processes the string and removes any punctuation.

Output:

The cleaned string (without punctuation) is printed.

Sort the Words in a Sentence Alphabetically

Input:

The program asks the user to input a sentence.

Splitting the Sentence into Words:

This splits the input sentence into individual words by spaces and stores them in the `words` list.

Sorting the Words Alphabetically:

The list of words is sorted in alphabetical order.

Uses the default lexicographical order, which works for most alphabetic characters.

Joining Words into a Sentence:

The sorted list of words is joined back into a single string with spaces between the words.

Output:

The sorted sentence is printed to the console.

A screenshot of a Python IDE's terminal window. The window has a title bar with 'Python' and standard window controls. The terminal shows the execution of a script. The prompt is 'PS C:\Users\Usman Ghani\Desktop\myworld>'. The command executed is '& "C:/Program Files/Python312/python.exe" "c:/Users/Usman Ghani/Desktop/myworld/AI_LAB_Task_4.py"'. The output consists of several lines: 'Enter a credit card number: 02560108338832', 'The card number is valid.', 'Enter a string: Hello, World!', 'String after removing punctuation: Hello World', 'Enter a sentence: The quick brown fox jumps over the lazy dog', and 'Sorted sentence: The brown dog fox jumps lazy over quick the'. The prompt 'PS C:\Users\Usman Ghani\Desktop\myworld>' is shown again at the end.

```
PS C:\Users\Usman Ghani\Desktop\myworld> & "C:/Program Files/Python312/python.exe" "c:/Users/Usman Ghani/Desktop/myworld/AI_LAB_Task_4.py"
Enter a credit card number: 02560108338832
The card number is valid.
Enter a string: Hello, World!
String after removing punctuation: Hello World
Enter a sentence: The quick brown fox jumps over the lazy dog
Sorted sentence: The brown dog fox jumps lazy over quick the
PS C:\Users\Usman Ghani\Desktop\myworld>
```
